Battery Charging Conditions
The following conditions may be observed during cold-start voltage tests until temperatures of electrical system components stabilize. The time it takes to reach optimum voltage and amps will vary with engine speed, load, and ambient temperature.

Maintenance/Low Maintenance Lead-Acid Battery:
Traditional lead acid batteries require lowest charge voltage of all vehicle battery chemistries. Battery cells must be maintained by periodically topping off with distilled water as required.

Maintenance-free Lead-Acid Battery:
Maintenance-free batteries are similar to Maintenance/Low Maintenance batteries, but may require slightly higher charge voltage.

Deep-cycle/Marine Maintenance-free Battery:
Charge acceptance of these batteries may display characteristics similar to maintenance-free batteries and may charge faster due to generally lower capacity relative to size.

AGM (Absorbed Glass Mat) Maintenance-free Battery:
These dry-cell batteries respond better than standard maintenance-free batteries. If battery state of charge (SOC) drops to 75% or less, batteries should be recharged to 95% or higher separately from engine charging system to avoid damaging charging system components and to provide best overall performance. Charge acceptance of these batteries may display characteristics similar to maintenance batteries, but may require higher charge voltage and will draw significant current (<100 amps) when under 50% SOC.

Lithium Battery:
Lithium batteries have unique charging characteristics that differ from lead acid. These batteries require charging systems configured specifically for lithium battery chemistries. Contact CEN for more information on lithium battery charging systems and components.

Testing Guidelines
Professional service technicians rely on the following guidelines when testing electrical components.

Voltage testing:
- Set meter to proper scale and type (AC or DC).
- Be sure to zero the meter scale or identify the meter burden by touching meter leads together. Meter burden must be subtracted from final reading obtained.
- Be sure the meter leads touch source area only. Prevent short circuit damage to test leads or source by not allowing meter leads to touch other pins or exposed wires in test area.
- Be sure to use CEN tools designed especially for troubleshooting CEN alternators when available.

Resistance (ohm) testing:
- Set meter to proper scale.
- Be sure to zero the meter scale or identify the meter burden by touching meter leads together. Meter burden must be subtracted from final reading obtained.
- Be sure meter leads touch source area only. Allowing fingers or body parts to touch meter leads or source during reading may alter reading.
- Be sure reading is taken when source is at 70ºF. Readings taken at higher temperatures will increase the reading. Conversely, readings taken at lower temperatures will decrease the reading.
- Be sure to test directly at the source. Testing through extended harnesses or cable extensions may increase the reading.
- "OL" as referenced in this document refers to open circuit: "infinite" resistance, typically in very high kilo- or megaohm range depending on meter and settings.

Diode testing:
- Diodes allow current to flow in one direction only. Typical voltage drop in forward bias can range from 0.1-0.85V. Meter should read OL in reverse bias. Check meter user manual for meter-specific testing guidelines.

Voltage drop testing:
- Measure voltage between B+ on alternator or power source and B- (ground) on alternator or source. Record reading. Move to batteries or other power source and measure again between B+ and B- terminals on battery or other power source. The difference between the two readings represents voltage lost within circuit due to, but not limited to, inadequate cable gauge or faulty connections.
- Voltage drop measurements must be taken with all electrical loads or source operating.

Dynamic/Live testing (Connecting power and ground to component to test operation/function out of circuit):
- Connect jumper leads directly and securely to power source contacts of component being tested.
- Make any connection to power and ground at power supply or battery source terminals. Do not make connection at component source terminals, as that may create an arc and damage component source terminals.
CEN C708 Alternator
Description and Operation

C708 28 V, 330 A alternator is internally rectified. All windings and current-transmitting components are non-moving, so there are no brushes or slip rings to wear out. Energize switch activates regulator at E or IGN terminal on regulator. Field coil is then energized. Regulator maintains alternator output voltage at regulated setting as vehicle electrical loads are switched on and off. Alternator output current is self-limiting and will not exceed rated capacity of alternator.

A2-316 regulator furnished with some units has an R or P terminal that can provide an optional AC voltage tap. Regulator also provides overvoltage cutout (OVCO).

A2-316 Regulator
DESCRIPTION AND OPERATION

A2-316 Regulator with OVCO is either attached directly to the outside of alternator or remote-mounted.

Main diagnostic feature of either regulator is tricolored LED next to harness receptacle on regulator. LED works like a voltmeter, measuring charging voltage. See Table 2 on page 4 for diagnostic features and LED explanations.

Regulators with OVCO (overvoltage cutout) will trip at vehicle electrical system voltages above 32 volts that exist longer than 3 seconds. OVCO feature detects high voltage and reacts by signaling relay in F+ alternator circuit to open. This turns off alternator (LED is flashing RED light). Restarting engine resets OVCO circuit. Regulator regains control of alternator output voltage.

Basic Troubleshooting
1. **Inspect charging system components for damage**
   Check connections at B– cable, B+ cable, and regulator harness. Repair or replace any damaged component before electrical troubleshooting.

2. **Inspect vehicle battery connections**
   Connections must be clean and tight.

3. **Determine battery voltage and state of charge**
   If batteries are discharged, recharge or replace batteries as necessary. Electrical system cannot be properly tested unless batteries are charged 95% or higher.

4. **Connect meters to alternator**
   Connect red lead of DMM to alternator B+ terminal and black lead to alternator B– terminal. Clamp inductive ammeter on B+ cable.

5. **Operate vehicle**
   Observe charge voltage. If charge voltage is above 32 volts, immediately shut down system. Electrical system damage may occur if charging system is allowed to operate at high voltage. Go to Table 1 at left.

   If voltage is at or below regulator setpoint, let charging system operate for several minutes to normalize operating temperature.

6. **Observe charge volts and amps**
   Charge voltage should increase and charge amps should decrease. If charge voltage does not increase within ten minutes, continue to next step.

7. **Battery**
   Battery is considered fully charged if charge voltage is at regulator setpoint and charge amps remain at lowest value for 10 minutes.

8. **If charging system**
   If charging system is not performing properly, go to Chart 3, page 5.
Troubleshooting

Shut down vehicle and restart engine. If alternator functions normally after restart, a “no output condition” was normal response of voltage regulator to “high voltage” condition. Inspect condition of electrical system, including loose battery cables, both positive and negative. If battery disconnects from system, it could cause “high voltage” condition in electrical system, causing OVCO circuit to trip.

If you have reset alternator once, and electrical system returns to normal charge voltage condition, there may have been a one time, high voltage spike, causing OVCO circuit to trip.

If OVCO circuit repeats cutout a second time in short succession and shuts off alternator F+ circuit, try third restart. If OVCO circuit repeats cutout, go to Chart 2.

Chart 1 – No Air-Conditioning/NO ALT OUTPUT Light On

With engine running, verify operation of charging system. Is regulator setpoint voltage present?

Yes | No
---|---

Go to Chart 3.

Connect DMM red lead to R or P terminal on regulator. Connect black lead to alternator B– terminal. Is 12 V to 18 V present?

Yes | No
---|---

Stop engine. Alternator is good. Check vehicle wiring.

Stop engine. Unplug alternator-to-regulator harness. Connect DMM red lead to socket D on alternator-to-regulator harness plug. Connect black lead to alternator B+ terminal. Does continuity exist?

Yes | No
---|---

Regulator is defective.

Alternator is defective.

---

Chart 2 – RED LED Flashing – No Alternator Output – Test OVCO Circuit

With engine off, unplug alternator-to-regulator harness. Connect DMM red lead to socket B on alternator-to-regulator harness plug. Connect black lead to socket C on same plug. Does resistance measure about 1.2 ohms?

Yes | No
---|---

Connect DMM red lead to socket B on alternator-to-regulator harness plug. Connect black lead to alternator B– terminal. Does continuity exist?

Yes | No
---|---

Alternator is defective.

Regulator is defective.
